Complex Hyperbolic Geometry Oxford Mathematical Complex hyperbolic geometry is a particularly rich field, drawing on Riemannian geometry, complex analysis, symplectic and contact geometry, Lie group theory, and harmonic analysis. The boundary in complex hyperbolic spaces, known as spherical CR or Heisenberg geometry, reflects this richness.

Abstract: In this paper we study discreteness of complex hyperbolic triangle groups of type $(2, 2, 2)$, i.e., groups of isometries of the complex hyperbolic plane generated by three complex reflections of orders in complex geodesics with pairwise distances θ . For fixed θ , the parameter space of such groups is of real dimension one. We determine intervals in this

In hyperbolic geometry, the shortest path, or "geodesic," between two points is the path that travels through the fewest possible fishes to get from one point to the other. Such a path, it turns out, is always a semicircle perpendicular to the boundary of the disk; the semicircles that go through the fishes' spines are examples.

where A consists of the diagonal matrices in $GL(n, \mathbb{C})$. This space naturally arises in the harmonic analysis on the hermitian symmetric space $GL(n, \mathbb{C}) / U(n-1, 1)$. It is shown here that these double cosets also represent a class of basic invariants related to complex hyperbolic geometry.
